

Summer 2026

IDX Exchange – Agentic AI Engineer Internship

Andrew Kim

I learned what it actually takes to deploy an AI agent that talks to a real SQL database, not just a demo chatbot. Most of the value was wiring: WhatsApp in, skills, then an orchestrator that decides search vs market vs recs vs email, then SQL/Python out. Once that path existed, the framework clicked. I can see using the same setup on other projects instead of starting from scratch every time.

This was my first time using TypeScript and JavaScript, and the learning curve was steep. I spent a lot of time on language/tooling instead of product. I also had never shipped something fully deployable before, so getting it live (bot, env, database, email) was harder than building a feature in isolation.

Tokens were a big problem. Follow-ups and mixed queries got expensive and messy when the model rewrote or expanded the user's text.

If I did this again, I would flip the order: lock orchestration first (what each message is, which agent runs, what gets passed through verbatim), then build the skills on top of that. We did a lot of skill and query work before the routing was solid, and that made later bugs harder to unwind.
